SPECIFICATION

608082

TITLE OF THE INVENTION

POLYMER ELECTROLYTE FUEL CELL

CROSS-REFERENCE TO RELATED APPLICATION

This application is related to Japanese Patent

- 5 Application No.2001-62403 filed on March 6, 2001, whose
priority is claimed under 35 USC § 119, the disclosure of
which is incorporated by reference in its entirety.

BACKGROUND OF THE INVENTION

1.Field of the Invention

- 10 The present invention relates to a polymer electrolyte
fuel cell. More particularly, in the polymer electrolyte fuel cell,
an oxygen-containing hydrocarbon is introduced as a material
for fuel from a supply section for supplying the material for
fuel, the material for fuel is decomposed by a biochemical
15 catalyst to generate hydrogen as fuel before the material for
fuel reaches an anode of the polymer electrolyte fuel cell, and
the generated hydrogen is supplied to the anode.

2.Description of Related Art

- A fuel cell is provided with a cathode and an anode on
20 both sides of an electrolyte. The cathode (oxidizer electrode)
is supplied with an oxidizing gas such as oxygen, air or the
like and the anode (fuel electrode) is supplied with a fuel such
as hydrogen, a hydrocarbon or the like, so that an
electrochemical reaction is induced to generate electricity and
25 water.

Fuel cells are classified into a number of groups such as alkaline fuel cells, acid fuel cells, molten carbonate fuel cells, solid oxide fuel cells and polymer electrolyte fuel cells (PEFCs) according to their types of electrolytes. Of these fuel cells, the PEFCs have proton-conductive solid polymers as electrolytes and are systems using high-purity hydrogen gas as fuel.

Since the PEFCs can work effectively at low temperatures and have high output density, the PEFCs are very likely to be put in practical use for power generation for vehicles and for small-scale houses. However, the PEFCs have the disadvantage of requiring huge cylinders containing compressed hydrogen for supplying gaseous hydrogen as fuel. Or alternatively, hydrogen may be liquefied and stored in cylinders. However, the liquefaction of hydrogen needs cooling at an extremely low temperature of - 253°C. Furthermore, because liquefied hydrogen evaporates easily and leaks from gaps between metal molecules of the cylinders, hydrogen is consumed significantly. In an alternative way, hydrogen may be stored in a special metal referred to as a "hydrogen-occulsion alloy." However, in order to store a sufficient amount of hydrogen, a large amount of the alloy is required, and consequently, fuel supply systems become heavy (by Junji Kayukawa , *Trigger*, July 2000, page 14, THE NIKKAN KOGYO SHINBUN, LTD.). For the above-mentioned reasons,

the PEFCs have some problems with their fuel supply systems, and at present it is difficult to put the PEFCs into widespread use as transportable power sources.

There are reforming processes of using liquid fuels containing hydrogen and decomposing the liquid fuels to generate hydrogen. The reforming processes include a steam reforming process of applying steam of extremely high temperature for inducing reaction and a partial oxidizing process of feeding oxygen for inducing reaction. Methanol can be reformed at a relatively low temperature of 300°C as compared with gasoline, gas oil, propane, butane and methane. Since the temperature is still high, the size of reforming devices is difficult to reduce.

On the other hand, direct methanol-air fuel cells (DMFCs) are directly supplied with methanol as fuel. Since they can use proton-conductive polymers as electrolytes, the DMFCs can possibly work at temperatures lower than 10°C. Since the fuel is liquid and is easy to transport and store, the DMFCs are considered to be suitable for size reduction and transportabilization. Thus the DMFCs are regarded as very likely power sources for automobiles and power sources for mobile electronic equipment.

Direct methanol-air fuel cells using proton-conductive polymer membranes as electrolytes (PEM-DMFCs) have a structure in which porous electrodes carrying electrocatalysts

are formed on both faces of a membrane of a fluorinated polymer having sulfonic acid groups, for example, a thin membrane such as Nafion® manufactured by DuPont, in such a manner as the porous electrodes sandwich the polymer

- 5 membrane, the anode is directly supplied with an aqueous methanol solution and the cathode is supplied with oxygen or air. At the anode, methanol reacts with water to generate carbon dioxide, protons and electrons:

- 10 At the cathode, oxygen reacts with protons and electrons to generate water:

These reactions progress with the help of the electrocatalysts carried by the electrodes. Theoretical voltage of these

- 15 reactions is 1.18 V, however in practical cells, the actual voltage is lower than the theoretical voltage for various reasons.

Platinum catalyzes the reaction of methanol with water and is an excellent anode catalyst. General mechanism
20 of the reaction of platinum with methanol is represented by the following chemical formulae:

- 25 $\text{Pt}-\text{COH} \rightarrow \text{Pt}-\text{CO} + \text{H}^+ + \text{e}^-$

However, the surface of the platinum electrocatalyst is poisoned with CO generated from methanol during the reactions. Consequently, the reaction area of the platinum electrocatalyst decreases, and therefore, the performance of cells declines.

In order to prevent the platinum electrocatalyst from being poisoned with CO, measures are taken to improve a surface structure of the platinum electrocatalyst or to add different metals such as Ru, Sn, W and the like to platinum. However, the different metals have lower catalytic activities to methanol than platinum, and to compensate that, the reaction temperature needs to be elevated. If the reaction temperature is high, methanol penetrates through the proton-conductive polymer electrolyte membrane (Nafion® membrane, Dow® membrane, Aciplex® membrane, Flemion® membrane)-from an anode side of the membrane to reach the cathode, and directly reacts with an oxidizer on the electrocatalyst of the cathode. This phenomenon is referred to as cross-over, which is a short-circuit problem. Also, the elevation of the reaction temperature is not suitable for power sources for mobile electronic equipment which needs to be operated at relatively low temperatures.

Bacteria such as Clostridia and Bacilli are known to decompose oxygen-containing hydrocarbons and produce water

and carbon dioxide through sugar fermentation (Nikkei Latest
Biotechnological Terms Dictionary, 4th edition, edited by
Nikkei Bio-tech, Nikkei Business Publications, Inc., page 346).
In order to measure the amount of hydrogen produced by such
5 bacteria, an example is reported in which the produced
hydrogen is supplied to the anode of a fuel cell and the amount
of generated electricity is measured. However, this is not put
into practical use as a polymer electrolyte fuel cell (Japanese
Unexamined Patent Publication No. HEI 7(1995)-218469).

10 Accordingly, there is a demand for a polymer
electrolyte fuel cell which uses an oxygen-containing
hydrocarbon such as methanol as a material for fuel and can
generate electricity at low temperatures with good efficiency.

SUMMARY OF THE INVENTION

15 An object of the present invention is to provide a
polymer electrolyte fuel cell wherein a supplied
oxygen-containing hydrocarbon is passed through a layer
containing a biochemical catalyst comprised of a
hydrogen-generative anaerobic bacterium, a
20 hydrogen-generative yeast, a hydrogen-generative enzyme
and/or the like and thereby the oxygen-containing
hydrocarbon is decomposed to produce hydrogen, which is
supplied as fuel to the anode of the polymer electrolyte fuel
cell.

25 The present invention provides a polymer electrolyte

fuel cell comprising a housing provided with an anode-side supply inlet for supplying a material for fuel; an anode and a cathode accommodated in the housing to sandwich a polymer electrolyte membrane; and a layer containing a biochemical catalyst which decomposes the material for fuel to generate fuel, the layer being formed between the anode-side supply inlet and the anode.

Further the present invention provides a polymer electrolyte fuel cell comprising: a housing provided with an anode-side supply inlet for supplying a material for fuel, the anode-side supply inlet being connected to a supply section for supplying the material for fuel; an anode and a cathode accommodated in the housing to sandwich a polymer electrolyte membrane; and a filter containing a layer containing a biochemical catalyst which decomposes the material for fuel to generate fuel, the filter being formed in the supply section.

These and other objects of the present application will become more readily apparent from the detailed description given hereinafter. However, it should be understood that the detailed description and specific examples, while indicating preferred embodiments of the invention, are given by way of illustration only, since various changes and modifications within the spirit and scope of the invention will become apparent to those skilled in the art from this detailed

description.

BRIEF DESCRIPTION OF THE DRAWINGS

Fig. 1 is a schematic sectional view of a polymer electrolyte fuel cell whose anode-side collector is also used as a biochemical catalyst layer in accordance with the present invention; and

Fig. 2 is a schematic sectional view of a polymer electrolyte fuel cell provided with a filter containing a biochemical catalyst layer for decomposing a hydrocarbon within a fuel supply path before the fuel is supplied to the anode of the cell in accordance with the present invention.

DESCRIPTION OF THE PREFERRED EMBODIMENTS

The housing for accommodating the polymer electrolyte fuel cell usable in the present invention may be one formed of an electrically insulative resin such as acrylic resin, polypropylene resin, polyethylene terephthalate resin, polycarbonate resin, polyether ether ketone resin, polyamide resin or the like. Among these, one formed of acrylic resin is preferred.

In the present invention, the supply inlet for supplying the material for fuel is provided on an anode side of the housing. The supply section for supplying the material for fuel includes all members used for supplying the material for fuel to the polymer electrolyte fuel cell. For example, the supply section includes a pipe for connecting the supply inlet

to a generator which generates the material for fuel, and valves and pipes between the generator and the supply inlet. The supply section may be formed integrally with the housing or may be detachably attached to the supply inlet of the housing.

- 5 In the case where the supply section is formed integrally with the housing, the supply section is a part of the polymer electrolyte fuel cell, and the polymer electrolyte fuel cell as a whole becomes smaller in size and simpler in shape. On the other hand, in the case where the supply section is detachably
- 10 attached to the supply inlet of the housing, the supply section is attached to the housing via the supply inlet when the polymer electrolyte fuel cell is used, and the supply section can be detached when the supply section is not required. Therefore, it is also possible to reduce the size of the polymer
- 15 electrolyte fuel cell. An inlet for supply an oxidizer may also be provided on a cathode side of the housing.

The polymer electrolyte membrane may be formed of a resin having, as cation exchange groups, sulfonic acid groups, phosphonic acid groups, phenolic hydroxyl groups or

20 fluorinated carbon and sulfonic acid groups, PSSA-PVA (polystyrene sulfonic acid polyvinyl alcohol copolymer), PSSA-EVOH (polystyrene sulfonic acid ethylenevinyl alcohol copolymer) and the like. Among these resins, is preferred an ion exchange resin having fluorinated carbon and sulfonic acid

25 groups, and more particularly, Nafion® (tradename,

ex-DuPont) is used. The polymer electrolyte membrane is obtained by forming a precursor of a resin into a membrane by a known process such as heat press molding, roll molding, extrusion or the like and hydrolyzing and treating the formed
5 membrane to be in acid form. The polymer electrolyte membrane may also be obtained by solvent casting from a solution of a fluorinated cation exchange resin in a solvent such as alcohol or the like.

The anode and the cathode used in the present
10 invention may be formed by making water repellant a porous substrate of carbon, carbon paper, formed carbon, sintered carbon, sintered metal, foamed metal, metal fiber aggregate or the like. These electrodes may be used together with electrocatalysts of precious metals. Besides platinum, gold,
15 palladium and ruthenium may be used singly or as an alloy for the electrocatalysts of precious metals, for both the cathode and anode. An alloy of platinum and ruthenium is preferred for the electrocatalyst of the anode. The amount of the electrocatalyst may be 0.01 mg/cm² to 10 mg/cm², preferably
20 0.1 mg/cm² to 0.5 mg/cm² with respect to the electrode.

The electrocatalyst can be attached to the electrodes by the following process. For example, a mixture of fine particles of platinum and ruthenium, as it is or carried on a carbon having a large surface area, is mixed with an alcohol
25 solution containing the polymer electrolyte and

polytetrafluoroethylene which serves as a binder and as a water repellant. The resulting mixture is sprayed onto the porous electrode, for example, of carbon paper and coupled to the polymer electrolyte by hot press (U.S. Patent No. 5,599,638.

- 5 Alternatively, a mixture of fine particles of platinum and ruthenium or its oxide, as it is or carried on a carbon having a large surface area, is mixed with an alcohol solution containing the polymer electrolyte, and this electrocatalyst mixture solution was applied onto a plate of
- 10 polytetrafluoroethylene. After being dried, the electrocatalyst mixture is peeled off the polytetrafluoroethylene plate, transferred onto the porous electrode of carbon paper or the like, and coupled to the polymer electrolyte by hot press (X.Ren et al., *J.Electrochem.Soc.*, 143. L12(1996)).

- 15 In the present invention, the biochemical catalyst for generating fuel by decomposing the material for fuel is one or more species selected from the group consisting of hydrogen-generative anaerobic bacteria such as Clostridia (e.g., clostridium butyricum, clostridium acetobutylicum),
- 20 Lactobacilli (e.g., Lactobacillus pentoaceifus), and photosynthetic bacteria including Rhodospirilli (e.g., Rhodospirillum rubrum) and Rhodopseudomonas (e.g., Rhodopseudomonas spheroides); hydrogen-generative yeasts such as methylotrophic yeast; and hydrogen-generative
- 25 enzymes such as methanol-assimilating enzyme, methanol

dehydrase and formate-hydrogen lyase. Among these biochemical catalysts, a combination of clostridium butyricum and formate-hydrogen lyase is preferred.

In the present invention, the layer containing the biochemical catalyst may be located within the fuel cell, i.e., between the anode and the supply inlet on the anode side for supplying the material for fuel, or may be located in the supply section for supplying the material for fuel. More particularly, in the case where the layer exists between the anode and the supply inlet within the fuel cell, the layer may be in the form of a filter in the supply inlet, or may also serve as an anode-side collector of the fuel cell. In the case where the layer exists within the supply section, the layer may be in the form of a filter or a cartridge comprising the layer in the supply section which is formed integrally with or separately from the housing of the polymer electrolyte fuel cell.

A collector used in the present invention may be formed by making water repellant a porous substrate of carbon paper, formed carbon, sintered carbon, carbon fiber, carbon fiber paper, sintered metal, foamed metal, metal fiber aggregate or the like. Among these materials, carbon fiber paper is preferred. The filter as the layer containing the biochemical catalyst may be formed of a material similar to that of the collector such as carbon fiber.

The layer containing the biochemical catalyst is

produced by fixing the biochemical catalyst onto a layer of a porous material such carbon black, acetyl cellulose, collagen · polyvinyl alcohol, zeolite, precipitated silica or the like. As techniques for fixing the biochemical catalyst, may be

5 mentioned the technique of covalent-bonding the biochemical catalyst to a fixation carrier, the technique of binding the biochemical catalyst by adsorption, an envelope fixation technique of enveloping the biochemical catalyst with a polymeric substance, and other techniques. The fixing
10 techniques may be selected depending upon their compatibility with the biochemical catalyst. For example, a culture liquid of the biochemical catalyst may be put into and adsorbed by the fixation carrier located in a desired place for forming the layer. The culture liquid of the biochemical catalyst is
15 prepared beforehand by cultivating the biochemical catalyst in a liquid medium such as ATOC38, liver-liver broth, thioglycolate medium or cooked meat (CM) medium of pH 2 to 8 at 10 to 40°C for 0.5 to 20 days. If the biochemical catalyst is an anaerobic bacterium, the cultivation may preferably be
20 carried out under oxygen-free conditions. More particularly, atmosphere is replaced by nitrogen. As examples of the fixation carrier, may be mentioned water-repellant porous substrates such as carbon paper, formed carbon, sintered carbon, carbon fiber, sintered metal, foamed metal, metal fiber
25 aggregate and the like.

As examples of the material for fuel used in the present invention, may be mentioned water-soluble

hydrocarbons decomposable by the biochemical catalyst, including for example alcohols (e.g., methanol, ethanol,

isopropyl alcohol, glycol, etc.); polysaccharides (e.g., glucose, etc.); oxygen-containing hydrocarbons such as aldehydes,

ketones, formic acid, acetic acid and the like which are

intermediate products in the process in which the

above-mentioned alcohols and polysaccharides are changed

into hydrogen and carbon dioxide gas through oxidation. As

the material for fuel, is selected one which is decomposed and finally generates hydrogen depending upon a selected

combination of biochemical catalysts. For example, if the

biochemical catalyst is a combination of a hydrogen-generative

anaerobic bacterium belonging to the genus Clostridium and

formate-hydrogen lyase, the material for fuel is preferably

methanol.

In this case, methanol is oxidized to generate

formaldehyde and then formic acid, which is formate-ionized.

The generated formate ions produce hydrogen and carbon

dioxide gas due to the action of formate-hydrogen lyase.

The produced hydrogen is then supplied to the anode

of the polymer electrolyte fuel cell, where hydrogen is oxidized to produce protons and electrons. The resulting protons migrate through the electrolyte toward cathode. On the cathode, protons react with oxygen to produce water. The electrons travel from the anode to the cathode through an external circuit, producing an electric current. The produced carbon dioxide gas is discharged to the outside of the fuel cell system together with excess fuel.

Since water is a reaction medium for the biochemical catalyst decomposing the oxygen-containing hydrocarbon, the oxygen-containing hydrocarbon is preferably water-soluble. The oxygen-containing hydrocarbon may be supplied as it is or in the form of an aqueous solution, but is preferably supplied in the form of an aqueous solution.

EXAMPLES

The present invention is now described in detail with reference to examples, which are only for general illustration and should not be construed to limit the present invention.

Example 1

A polymer electrolyte fuel cell was produced as follows. Platinum was made carried by 5 g of carbon in an amount of 10 wt %. The resulting carbon was attached to a porous electrode (anode) 4 and a porous electrode (cathode) 5 (the amount of the electrocatalyst is 17 mg/cm² of the electrodes).

The electrodes 4 and 5 were coupled by hot press to both faces of an electrolyte membrane 3 formed of Nafion® manufactured by DuPont, to form a catalyst-integrated electrolyte membrane.

On both sides of the resulting electrolyte membrane, an

5 anode-side collector 6 and a cathode-side collector 7 were formed of carbon fiber. The polymer electrolyte fuel cell was accommodated in a housing (A)1 and a housing (B)2 which were formed of an acrylic resin which was an electrically insulative resin. The housing (A)1 was provided with a supply inlet 8 for a material for fuel and a fuel discharge outlet 9.

10 The housing (B) was provided with an air supply inlet 10 and an air discharge outlet 11. Contact faces of the housings (A)1 and (B)2 were sealed with a silicone sheet 16 for preventing leakage of hydrogen, air or oxygen and were fastened with a

15 bolt 12. For taking out electricity efficiently, an aluminum negative electrode 14 and an aluminum positive electrode 13 were connected to one end and another end of copper springs 15 which were located on the outer sides of the anode 4 and the cathode 5. A mixture liquid, 3 mL, of formate-hydrogen

20 lyase and Clostridium butyricum cultivated using a liquid medium ATOC38 of a starting pH 8.0 at 30°C for 10 days was put and fixed in the anode-side collector 6 (see Fig. 1).

Example 2

A polymer electrolyte fuel cell is produced in the same
25 manner as Example 1 except that the bacterium and the

enzyme were not used for the anode-side collector 6. Further the polymer electrolyte fuel cell of Example 2 was provided with a filter 18 connected to the supply inlet 8 for the material for fuel by a connection pipe 17. The filter 18 was formed of
5 the same material as the collectors 6 and 7. *Clostridium butyricum* and formate-hydrogen lyase were fixed in part of the filter by the aforesaid method. (see Fig. 2).

Reference Example 1

A polymer electrolyte fuel cell is produced in the same
10 manner as Example 1 except that the bacterium and the enzyme were not used for the anode-side collector 6.

Evaluation Test of polymer electrolyte fuel cells

An aqueous solution of methanol was fed via the supply inlet 8 for the material for fuel of the polymer
15 electrolyte fuel cell of Example 1. When the aqueous solution of methanol passed through the anode-side collector, hydrogen and carbon dioxide gas were generated due to the action of *Clostridium butyricum* and formate-hydrogen lyase. Carbon dioxide gas was discharged from the fuel discharge outlet 9 to
20 the outside of the polymer electrolyte fuel cell together with excess hydrogen. On the other hand, the generated hydrogen was fed to the anode 4, and was ionized to generate protons due to the action of the platinum electrocatalyst provided in the anode. The generated protons passed through the
25 electrolyte membrane 3 and reacted with oxygen ions to

produce water on the cathode side. Electrons generated during this reaction are taken out of the fuel cell system, whereby electricity was generated constantly for 5 hours.

- An aqueous solution methanol was fed via the supply inlet 8 for the material for fuel of the polymer electrolyte fuel cell of Reference Example 1. The resulting generation of electricity declined gradually, and stopped after three hours.

EFFECT OF THE INVENTION

- As clearly seen from the examples and reference example, the polymer electrolyte fuel cell of the present invention generated electricity more efficiently than the ordinary methanol fuel cell which used an oxygen-containing hydrocarbon as fuel but did not use biochemical catalysts.
- According to the present invention, since carbon monoxide is not generated unlike the case where an oxygen-containing hydrocarbon is fed directly to the anode, the poisoning of platinum, ruthenium or the like used for the anode catalyst can be avoided. Further the fuel cell can work at low temperatures.
